The \texttt{\texttt{l3tl-analysis}} package: analysing token lists

\texttt{The \LaTeX3 Project}†

Released 2015/09/26

\section{\texttt{l3tl-analysis} documentation}

This module mostly provides internal functions for use in the \texttt{l3regex} module. However, it provides as a side-effect a user debugging function, very similar to the \texttt{\ShowTokens} macro from the \texttt{tex} package.

\begin{verbatim}
\tl_show_analysis:N \tl_show_analysis:n \{\langle token list\rangle\}
\end{verbatim}

Displays to the terminal the detailed decomposition of the \langle token list\rangle into tokens, showing the category code of each character token, the meaning of control sequences and active characters, and the value of registers.

\subsection{Internal functions}

\begin{verbatim}
\s__tl
\end{verbatim}

The format used to store token lists internally uses the scan mark \texttt{\s__tl} as a delimiter.

\begin{verbatim}
\_tl_analysis_map_inline:nn \_tl_analysis_map_inline:nn \{\langle token list\rangle\} \{\langle inline function\rangle\}
\end{verbatim}

Applies the \langle inline function\rangle to each individual \langle token\rangle in the \langle token list\rangle. The \langle inline function\rangle receives three arguments:

- \langle tokens\rangle, which both \texttt{o}-expand and \texttt{x}-expand to the \langle token\rangle. The detailed form of \langle token\rangle may change in later releases.

- \langle catcode\rangle, a capital hexadecimal digit which denotes the category code of the \langle token\rangle (0: control sequence, 1: begin-group, 2: end-group, 3: math shift, 4: alignment tab, 6: parameter, 7: superscript, 8: subscript, A: space, B: letter, C: other, D: active).

- \langle char code\rangle, a decimal representation of the character code of the token, \texttt{-1} if it is a control sequence (with \langle catcode\rangle \texttt{0}).

\end{footnotes}
For optimizations in \texttt{l3regex} (when matching control sequences), it may be useful to provide a \texttt{\_\_tl\_analysis\_from\_str\_map\_inline\:nn} function, perhaps named \texttt{\__-str\_analysis\_map\_inline\:nn}.

### 1.2 Internal format

The task of the \texttt{l3tl\_analysis} module is to convert token lists to an internal format which allows us to extract all the relevant information about individual tokens (category code, character code), as well as reconstruct the token list quickly. This internal format is used in \texttt{l3regex} where we need to support arbitrary tokens, and it is used in conversion functions in \texttt{l3str\_convert}, where we wish to support clusters of characters instead of single tokens.

We thus need a way to encode any \texttt{⟨token⟩} (even begin-group and end-group character tokens) in a way amenable to manipulating tokens individually. The best we can do is to find \texttt{⟨tokens⟩} which both \texttt{o}\text{-}expand and \texttt{x}\text{-}expand to the given \texttt{⟨token⟩}. Collecting more information about the category code and character code is also useful for regular expressions, since most regexes are catcode-agnostic. The internal format thus takes the form of a succession of items of the form

\[
⟨\text{tokens}⟩ \texttt{\_\_t}  \langle\text{catcode}\rangle \langle\text{char code}\rangle \texttt{\_\_t}
\]

The \texttt{⟨tokens⟩} \texttt{o} and \texttt{x}\text{-}expand to the original token in the token list or to the cluster of tokens corresponding to one Unicode character in the given encoding (for \texttt{l3str\_convert}). The \texttt{⟨catcode⟩} is given as a single hexadecimal digit, 0 for control sequences. The \texttt{⟨char code⟩} is given as a decimal number, \texttt{-1} for control sequences.

Using delimited arguments lets us build the \texttt{⟨tokens⟩} progressively when doing an encoding conversion in \texttt{l3str\_convert}. On the other hand, the delimiter \texttt{\_\_t} may not appear unbraced in \texttt{⟨tokens⟩}. This is not a problem because we are careful to wrap control sequences in braces (as an argument to \texttt{\exp\_not:n}) when converting from a general token list to the internal format.

The current rule for converting a \texttt{⟨token⟩} to a balanced set of \texttt{⟨tokens⟩} which both \texttt{o}\text{-}expands and \texttt{x}\text{-}expands to it is the following.

- A control sequence \texttt{\cs} becomes \texttt{\exp\_not:n { \cs } \_\_t} \texttt{0 -1 \_\_t}.
- A begin-group character \texttt{\{} becomes \texttt{\exp\_after:wN { \if\_false: \fi: \_\_t} 1 \langle\text{char code}\rangle \_\_t}.
- An end-group character \texttt{\}} becomes \texttt{\if\_false: \fi: \_\_t} \texttt{2 \langle\text{char code}\rangle \_\_t}.
- A character with any other category code becomes \texttt{\exp\_not:n \{⟨character⟩\} \_\_t \langle\text{hex catcode}\rangle \langle\text{char code}\rangle \_\_t}.
